### Communication test

Can a realistic multi-cohort manuscript exercise evidence-linked poster generation without redistributing a real paper or implying biomedical evidence?

Evidence: Abstract and Introduction, pp. 1-2

### Deterministic workflow

- Fixed seed generated 1,240 profiles
- 480 anonymous transcript-like features
- Nested elastic-net selection
- 12-feature score and shift testing

#### FOUR SYNTHETIC COHORTS

Discovery n=620 · Internal validation n=310  
External simulation A n=186 · External simulation B n=124  
All values are authored fixtures; no participant, specimen, institution, registry or external dataset exists.

Evidence: Abstract and Methods, pp. 1-2

### Generation to validation

### External simulations retained C-indices of 0.75 and 0.74

Synthetic baseline: 0.66 and 0.65 · software fixture, not clinical validation

Evidence: Results, pp. 1 and 3; Figure 2

### Discrimination across shifts

### Calibration and stress boundary

- External calibration slopes were 0.97 and 0.95.
- External absolute errors were 0.031 and 0.038.
- Aggregate coefficient-sign stability was 92% across 500 resamples.
- The most severe pre-specified shift reduced C-index by 0.04.

Evidence: Results, pp. 1, 3-4; Figures 3-4

AURORA-12 vs baseline C-index · Discovery 0.78 vs 0.68 · Internal 0.76 vs 0.67 · External A 0.75 vs 0.66 · External B 0.74 vs 0.65

### Calibration & stability

92%

coefficient-sign stability

0.97 / 0.95

external calibration slopes

0.031 / 0.038

external absolute errors

Evidence: Stability and calibration, p. 4

### Pre-specified stress test

### Supported conclusion

AURORA-12 is a controlled, rights-safe fixture for testing evidence-linked scientific communication. It supports no inference about real biology, prognosis, treatment or clinical utility. Every number, cohort, feature, author and institution is fictional.

Evidence: Discussion and Conclusion, p. 5
